STREADY

A Marathon Training Companion

UX Case Study • UI/UX Design Internship • September–October 2026
Skill Set Go 2026

Project overview
Stready (streak + steady) is a concept for runners who already have a training plan and want to track progress, stay accountable, and adjust sessions when everyday life interrupts their schedule.

1. The Problem

Runners preparing for a race may find it difficult to follow a structured plan when work, illness, unexpected events, or motivation changes disrupt the schedule. A training companion should help users recover from disruptions without replacing their judgment or an existing coach-created plan.

Design question: How might we help runners stay accountable to their existing training plan when real life gets in the way?

2. Target Users

Debut or self-training runners: runners preparing for a first race without a coach who may need structure, guidance, and accountability.
Experienced runners: runners who understand training but need flexibility when work or personal commitments interfere.

3. Research & Key Insights

Lightweight discovery included short interviews with two experienced runners. Follow-up conversations were used to explore the Reschedule / Adjust direction and refine the product concept.

- Runners may already follow a plan created by a coach; tracking and accountability can be more valuable than replacing that plan.
- Training recommendations should be options, not commands, because an app cannot fully understand sleep, stress, fatigue, and personal circumstances.
- Users should be able to understand why a recommendation is being shown, with relevant training context where available.
- Multiple alternatives may better preserve user control than a single fixed recommendation.

These findings informed the product direction: an existing-plan tracking and accountability companion first, with training suggestions as an optional feature.

4. Product Direction & Information Architecture

The core flow is: **Existing training plan** -> **Real-life disruption** -> **Review adjustment options** -> **Keep training on track**.

The main areas are Home / Dashboard, Training Calendar, Workout Log, Reschedule / Adjust, Workout Details, and Profile. The persistent bottom navigation covers Home, Calendar, Log, and Profile; Reschedule / Adjust is accessed contextually.

5. Design Decisions

Recommendations as options, not commands. Runners keep control over their decisions.
Existing plan first. Tracking, reminders, progress, and adjustments take priority over generating a new plan.
Contextual rescheduling. The rescheduling flow is reached from relevant training contexts.
Reusable design system. A Figma design system and component library were created to help keep the UI consistent. Insert final component and token screenshots in the evidence section.

6. Final Product Scope

The final screens in scope are Home, Training Calendar, Workout Log, and Reschedule. The interactive prototype is available at https://bit.ly/4yn8ep8.

7. Usability Testing

One participant completed a remote usability test using screen recording and post-task questions. The participant attempted three tasks: reschedule a training session, record a completed workout (6 km in 40 minutes), and check weekly progress. Difficulty ratings were collected on a 1–5 scale.

Task 1 — Rescheduling (2/5)

The participant needed time to discover the intended entry point, then reached the Reschedule page and understood the recommendation. The “Reschedule Manually” option did not have a sufficiently clear interactive affordance in the tested prototype.

Task 2 — Logging a workout (4/5)

The participant navigated to Workout Log but did not select “Add Workout,” assuming that reaching the page completed the task. They did not reach the workout input form.

Task 3 — Weekly progress (5/5)

The participant found the weekly progress information on Home and understood “65% Progress” and “Weekly Distance” without additional guidance.

Overall feedback

The participant liked the Training Calendar for viewing and organizing training. They also suggested a manual route map when recording a run, so a route could be shared in a story. This is a future feature suggestion, not a confirmed implementation.

8. Findings & Iteration Priorities

Finding	Implication
Reschedule discovery and manual option affordance need improvement	Strengthen the entry point and make interactive controls visually obvious
Add Workout was not recognized as the next step	Increase CTA prominence and clarify the action
Weekly progress was easy to find and understand	Preserve the information hierarchy that worked in this test

9. Limitations

Only one participant completed testing, although the initial target was two to three. The participant was a regular runner, but one person's experience cannot represent the broader running population. The findings should be treated as initial usability insights. Additional testing is needed to validate any design changes.

The prototype does not include authentication. Profile is intentionally lightweight, and connected-device integration is a placeholder. The manual route-map idea was feedback, not a built feature.

10. Reflection & Next Steps

The test showed that an information architecture can lead a participant to the correct page while still leaving the next action unclear. The next iteration should prioritize a more discoverable rescheduling entry point, a clearer “Add Workout” action, and stronger affordance for “Reschedule Manually.” After implementing and documenting any changes, test the updated flows with more runners.
